PROJECTED PARTICLE THEORY

A Speculative Conceptual Framework for Universe-Specific Particle Codes, Reality Stability, and Hypothetical Multiverse Transitions

Proposed by

Dharmesh Choudhary

Conceptual research paper • October 2026

Status: Preliminary hypothesis — not an experimentally verified physical theory.

This paper organizes an original speculative idea into a research-style format. It distinguishes the proposed model from established physics and does not claim that multiverse travel, projected particles, or the proposed mechanisms have been demonstrated.

ABSTRACT

The Projected Particle Theory (PPT), as proposed here, hypothesizes that reality may be associated with extremely small, individually unobservable entities called projected particles. The proposal suggests that many such particles form a closely packed collective structure, with negligible inter-particle distance, and that this structure underlies the observable universe. It further hypothesizes that each possible universe has a distinct particle code or arrangement, which helps define that universe's physical reality. A hypothetical "Super Projected Particle" is proposed as a common element that could be associated with multiple universes. The model also speculates that disturbing a universe-specific code or arrangement could destabilize reality, and that a controlled transition between universes would require some way of managing these interactions. These claims are conceptual and currently lack mathematical formulation, experimental evidence, and a known physical mechanism. The purpose of this paper is to define the proposal clearly and identify questions that would need to be answered before it could be evaluated scientifically.

Keywords: projected particles, particle code, reality structure, multiverse hypothesis, superposition, Super Projected Particle, speculative physics

1. Introduction

The Projected Particle Theory is a speculative conceptual model intended to explore whether the observable universe could be understood as the collective structure or projection of smaller, individually invisible entities. The idea was developed by the author while reflecting on fictional multiverse concepts, including those presented in the television series *Dark Matter* (2024). The series serves as inspiration, not as scientific evidence.

The central proposal is that the structure of a universe depends on the collective arrangement and a universe-specific code associated with its projected particles. Different hypothetical universes, such as the author's illustrative "Earth 401" and "Earth 502," would have different codes. The proposal asks whether such differences could explain why each universe has its own consistent reality and why transitioning between them, if possible, might require a special mechanism.

2. Core Postulates of the Proposed Model

2.1 Individual projected particles

Projected particles are hypothesized to be extremely small and individually invisible. Their existence is a postulate of this model, not an established discovery. The proposal treats them as more fundamental than ordinary visible structures, but it does not yet specify their mass, charge, spin, energy, or other measurable properties.

2.2 Collective structure and negligible separation

The model proposes that projected particles occur in very dense groups, with inter-particle distances that are negligible within the proposed framework. The collective structure, rather than an individual particle, is hypothesized to be associated with the visible universe. This is a conceptual claim: it does not yet explain how visibility, light, or matter would emerge from the proposed arrangement.

2.3 Universe-specific codes

Each hypothetical universe is proposed to have a distinct projected-particle code or arrangement. For illustration, "Earth 401" represents one possible universe and "Earth 502" another. Their codes would differ, and those differences would correspond to the rules or conditions of each universe. The model has not yet defined what a code physically consists of, where it is stored, or how particles interact with it.

2.4 The Super Projected Particle

The author proposes a hypothetical entity called the **Super Projected Particle**, which could be common to, or linked with, more than one universe. In the model, it might provide a shared connection during a hypothetical transition between universes. Its physical properties and the meaning of being "common" across universes remain undefined.

2.5 Reality stability and code disturbance

The model hypothesizes that a universe's stable reality depends on the integrity of its projected-particle code or arrangement. A disturbance could, according to the proposal, lead to a breakdown of the usual reality structure or a superposition-like condition. This is not a result established by quantum mechanics; the model would need to define "disturbance," "reality breakdown," and "superposition" precisely.

3. Hypothetical Multiverse Transition

The proposal asks whether a transition between universes could occur if the interaction between a person and their original universe's projected-particle arrangement were altered. The author has considered a special containment cube and a drug that temporarily diffuses brain electrical signals as possible fictional mechanisms. These are speculative narrative concepts, not known technologies or safe experimental methods.

In the proposed scenario, a transition would need to avoid an incompatible interaction between the particle code of the originating universe and that of the destination universe. The Super Projected Particle is suggested as a possible common link. However, no mechanism is currently known that would make this process physically possible, and interrupting brain activity is not known to enable travel between realities. No drug should be developed or used on the basis of this idea.

4. Relationship to Established Physics

Some themes in the proposal resemble broad questions studied in physics, but resemblance does not establish equivalence. The collective behaviour of many components is studied through statistical physics and emergence. Quantum field theory describes known elementary particles and their interactions using fields. Quantum superposition is a defined feature of quantum states, not a general synonym for uncertainty or a universe breaking apart. Modern relativity places a fundamental constraint on sending information or ordinary matter faster than light in vacuum, and no faster-than-light projected particle has been experimentally confirmed.

The Projected Particle Theory currently has no identified particle, mathematical equations, quantitative predictions, or experimental observations that distinguish it from existing models. Consequently, it should be described as a speculative hypothesis rather than a scientific theory validated by evidence.

5. Open Scientific Questions

• What measurable properties define a projected particle (for example, energy, mass, charge, or interaction strength)?

• What does the proposed particle “code” physically represent, and how could it be measured?

• How would the collective arrangement generate or relate to matter, light, space, and time?

• What does “negligible inter-particle distance” mean quantitatively?

• What observable result would indicate that a particle code or arrangement had been disturbed?

• How is the proposed Super Projected Particle different from other proposed particles, and what unique prediction follows from it?

• What evidence could distinguish this hypothesis from established physics or show that it is incorrect?

6. A Responsible Path for Further Development

The next step is not to assume that the proposal is proven, but to make its definitions more precise. First, specify each postulate in plain language. Second, identify which claims are assumptions and which are consequences of those assumptions. Third, look for conflicts with well-tested physics. Fourth, develop a measurable prediction that could in principle be falsified. Any proposed test should be theoretical or use established, safe scientific methods; human drug experiments or attempts to disrupt brain activity are not appropriate.

7. Conclusion

The Projected Particle Theory is an original speculative framework proposed by Dharmesh Choudhary. It brings together the ideas of individually invisible particles, a dense collective structure, universe-specific codes, a hypothetical Super Projected Particle, and possible reality instability following code disturbance. Its current value is as a clearly stated concept that can be questioned, refined, and compared with known physics. At present, it is not experimentally supported, and its multiverse-transition mechanism is not established. Further progress would require precise definitions, a coherent physical mechanism, and testable predictions.

References and scope note

This document is a conceptual write-up based on the author’s description of the hypothesis. It is not a peer-reviewed paper and does not claim experimental confirmation. For background reading, consult introductory materials on quantum mechanics, quantum field theory, special relativity, and the philosophy of scientific testing. The television series *Dark Matter* (2024) is a fictional inspiration only.
